

# Arbitrary Precision Math C++ Package

By: Henrik Vestermarck  
([hve@hvks.com](mailto:hve@hvks.com))

Revised: 6 August 2023

# Revision History

Revision Date	Change
2003/06/25	Initial Release
2007/08/26	Add the Floating point Epsilon function Add the ipow() function. Integer raise to the power of an integer
2013/Oct/2	Added new member functionality and expanded the explanation and usage of these classes.
2014/Jun/21	Cleaning up the documentation and adding a method to int_precision() and toString()
2014/Jun/25	Added abs(int_precision) and abs(float_precision)
2014/Jun/28	Updated the description of the interval packages
2016/Nov/13	Added the nroot()
2017/Jan/29	Added the transcendental constant $e$
2017/Feb/3	Added gcd(), lcm() and two new methods to int_precision(), even() & odd()
2019/Jul/22	Added fraction Arithmetic packages. Added more examples if usage in Appendix C & D
2019/Jul/30	Added 3 methods to Float_precision: .toFixed(), .toPrecision() & .toExponential()
2019/Sep/17	Change the class interface to move the sign out into a separate variable. int_precision_atoi() now also returns the sign instead of embedding it into the string
2020/Aug/12	Added Appendix E with compiler information
2021/Mar/22	Added missing information about Trigonometric functions for complex arguments and Hyperbolic functions for complex arguments
2021/Mar/24	Added the float precision operator %, %= (same as the function fmod)
2021/Jul/30	Added more functionality to the interval package e.g. hyperbolic, trigonometric functions, and interval constants. Fixed some typos in complex precision
1-Nov-2021	Revised completely to describe the new internal binary format for arbitrary precision. Added &=,  =, ^=, &,  , ^ as new operators for int_precision. Furthermore added the following new methods. testbit(), flipbit(), setbit(), resetbit(), ctz(), clz(), iszero(), number(). For float_precision the following method was added: number(), index(), size(), iszero(), toInteger(), toFraction()
11-Jan-2022	Added more constants to the _float_table() functions. _INVSQRT2, _SQRT2, _INVSQRT3, _SQRT3 and clean up the manual.
23-Mar-2022	Added _ONTENTH as a constant and introduce dynamic fixed-size integers
21-May-2022	Added log2() and AGM() for float_precision and .square() and .inverse() method
31-Oct-2022	Added nextafter() with the same functionality as in the C++ library. Also added methods: .succ() and .pred() to the float_precision class
12-Dec-2022	Added factorial(), fallingfactorial(), binomial() as int_precision functions. Added Bernoulli() as fraction_precision function and added a section for API method and API function for fraction_precision. Added bernoulli(), bernoulliPolynomials for float_precision objects

# Revision History

13-Jan-2022	Added the Euler-Mascheroni and the Catalan constant. Added the float precision function <code>tgamma()</code> , <code>beta()</code> , <code>erf()</code> and <code>erfc()</code>
17-Jan-2023	Added Lambert Wo function
20-Jan-2023	Added zeta function
25-Mar-2023	Added Stirling number of the first, second, and the third kind
11-May-2023	Added the computation of the Jacobi symbol, and the probabilistic primality tester. Miller-Rabin and Baillie PSW
20-Jun-2023	Added arbitrary precision pseudo-random number generators (PRNGs)
6-Aug-2023	Added arbitrary precision Fibonacci sequence

# Arbitrary Precision Math C++ Package

## Introduction

C++'s data types for integer, single and double precision floating point numbers, and the Standard Template Library (STL) complex class are limited in the amount of numeric precision they provide. The following table shows the range of the standard built-in and complex STL data type values supported by a typical C++ compiler:

Class	Storage Allocation (bytes)	Range
<i>short</i>	2	$-32768 \leq N \leq +32767$
<i>unsigned short</i>	2	$0 \leq N \leq 65535$
<i>int</i>	4	$-2147483646 \leq N \leq 2147483647$
<i>long</i>	4	$-2147483646 \leq N \leq +2147483647$
<i>unsigned int</i>	4	$0 \leq N \leq 4294967295$
<i>long long</i>	8	$-9223372036854775807 \leq N \leq 9223372036854775807$
<i>long long</i>	8	$0 \leq N \leq 18446744073709551615$
<i>int64_t</i>	8	$-9223372036854775807 \leq N \leq 9223372036854775807$
<i>uint64_t</i>	8	$0 \leq N \leq 18446744073709551615$
<i>float</i>	4	$1.175494351E-38 \leq  N  \leq 3.402823466E+38$
<i>double</i>	8	$2.2250738585072014E-308 \leq  N  \leq 1.7976931348623158E+308$
<i>complex</i>	4 or 8	See float and double

The above numeric precision ranges are adequate for most uses but are inadequate for applications that require either, very large magnitude whole numbers, or very large small and precise real numbers. When an application requires greater numeric magnitude or precision, other techniques need to be used.

The C++ classes described in this manual greatly extend the limited range and precision of C++'s built-in classes:

Class	Usage
<i>int_precision</i>	Whole (integer) numbers
<i>float_precision</i>	Real (floating point) numbers
<i>complex_precision</i>	Complex numbers
<i>interval_precision</i>	Interval arithmetic
<i>fraction_precision</i>	Fraction arithmetic

The two first classes, *int\_precision*, and *float\_precision* support basic arbitrary precision math for integer and floating point (real) numbers and are written as concrete classes. The *complex\_precision*, *interval\_precision*, and *fraction\_precision* classes are implemented as template classes, which support *int\_precision* or *float\_precision* (*float\_precision* is not supported in *fraction\_precision*) objects, as well as the ordinary C++ built-in *float* or *double* data types.

Both the *complex\_precision* and *interval\_precision* classes can work with each other; therefore, it is possible to create an interval object using a *complex\_precision* object, or a

# Arbitrary Precision Math C++ Package

complex object using `interval_precision` objects. Normally, `complex_precision` and `interval_precision` objects are built using `float_precision` objects.

This version of the manual describes the new internal binary format and the added functionality.

## Compiling the source code

The source consists of five header files and one C++ source file:

```
iprecision.h  
fprecision.h  
complexprecision.h  
intervalprecision.h  
fractionprecision.h  
precisioncore.cpp
```

The header files are used as include statements in your source file and your source file(s) need to be compiled together with `precisioncore.cpp` which contains the basic C++ code for supporting arbitrary precision.

The source has been developed, tested, and compiled under Microsoft Visual C++ 2022 compiler. See Appendix E for additional compiler info.

Configuration is not needed except for two options. By default, multi-threading is enabled and implemented where it makes sense. This will increase the performance of many operations. `HVE_THREAD` is defined by default in the file `precisioncore.cpp` and in case it should not be enabled then `undef` this definition.

The other configuration is in the file: `iprecision.h`

Here `#define _INT_PRECISION_FAST_DIV_REM`

This means that `int_precision` division/Remaining is carried out using `float_precision` division/remaining. There is a very efficient method for `float_precision` division that is faster than an `int_precision` division.

# Arbitrary Precision Math C++ Package

## Arbitrary Integer Precision Class

### Usage

To use the integer precision class the following include statement needs to be added to the top of the source code file(s) in which arbitrary integer precision is needed:

```
#include "iprecision.h"
```

An arbitrary integer precision number (object) is created (instantiated) by the declaration:

```
int_precision myVariableName;
```

An `int_precision` object can be initialized in the declaration in many different ways. The following examples show the supported forms for initialization:

```
int_precision i1(1);      // Decimal number
int_precision i2('1');    // Char number
int_precision i3("123");  // String
int_precision i4(0377);   // Octal
int_precision i5(0x9Af);  // Hexadecimal
int_precision i6(0b01011); // Binary
int_precision i7(i1);     // Another int_precision object
```

In the same manner, `int_precision` objects can also be initialized/modified directly after instantiation. For example:

```
int_precision i1 = 1;      // Decimal
int_precision i2 = '1';    // Char. Stored as the binary value of '1'
int_precision i3 = "123";  // String
int_precision i4 = 0377;   // Octal
int_precision i5 = 0x9Af;  // Hexadecimal
int_precision i6 = i1;     // Another int_precision object
```

Please note that decimal string can contain ' or \_ to make the number more readable. E.g.

```
int_precision i7 = "123'000'000";    // String
int_precision i8 = "123_000_000";    // String
```

The ' or \_ is simply ignored by the software

Initialization of `int_precision` creates an arbitrary precision integer variable that can grow to any arbitrary size. E.g. 1M digits, 1Billion digits, etc. However, it can also be fixed by limiting the size to any number of 64-bit trunks. E.g. to create an integer capable of holding 128 bits of information.

```
int_precision i128("235689", 2) ;    // 128bit fixed sized integer
int_precision i1024("235689", 16) ;   // 1024bit fixed sized integer
```

## Arbitrary Precision Math C++ Package

The 2<sup>nd</sup> optional parameter is the number of 64-bit trunks that the integer can hold. If omitted the number can growth arbitrary. A fixed-size integer can be changed to another fixed size or unlimited using the method `precision()`.

### Arithmetic Operations.

The arbitrary integer precision package supports the flowing C++ integer arithmetic operators: `+`, `-`, `++`, `--`, `/`, `*`, `%`, `<<`, `>>`, `+=`, `-=`, `*=`, `/=`, `%=`, `<=<=`, `>>=`, `|`, `&`, `^`, `|=`, `&=`, `^=`

The following examples are all valid statements:

```
i1=i2;
i1=i2+i3;
i1=i2-i3;
i1=i2*i3;
i1=i2/i3;
i1=i2%i3;
i1=i2>>i3;
i1=i2<<i3;
i1=i1&i2;
i1=i1|i2;
i1=i1^i2;
```

and

```
i1*=i2;
i1-=i2;
i1+=i2;
i1/=i2;
i1%=i2;
i1<=<=i2;
i2>>=i1;
i2&=i1;
i2|=i1;
i2^=i1;
```

Following are examples using the unary `++` (increment), `--` (decrement), and `-` (negation) (including `+` positive)

```
i1++;    // Post-increment
--i3;    // Pre-decrement
i2=-i1;
i2+=i1;
```

The following standard C++ test operators are supported: `==`, `!=`, `<`, `>`, `<=`, `>=`

```
if( i1 > i2 )
    ...
else
    ...
```

## Arbitrary Precision Math C++ Package

The `int_precision` package also includes 12 demotion member functions for converting `int_precision` objects to either `char`, `short`, `int`, `long`, `int64_t`, `long long` or the unsigned versions, unsigned `char`, unsigned `short`, unsigned `int`, unsigned `long`, unsigned `uint64_t`, unsigned `long long` or `float`, `double` standard C++ data types or the corresponding unsigned integer types.

Note: Overflow or rounding errors can occur.

```
int i;
double d;
int_precision ip1(123);

i=(int)ip1;      // Demote to int. Overflow may occur
d=(double)ip1;  // Demote to double. Overflow/rounding may occur
```

### Math Member Functions

The following set of public member functions is accessible for `int_precision` objects:

```
int_precision  abs( int_precision ); // abs(i)
int_precision  ipow( int_precision, int_precision ); // a^b
int_precision  ipow_modulo( int_precision, int_precision, int_precision ); //
a^b%c
bool           isprime( int_precision ); // Test number for a prime
int_precision  gcd(int_precision, int_precision ); //gcd(a,b)
int_precision  lcm(int_precision, int_precision ); //lcm(a,b)
int_precision_ iptoa()
```

### Input/Output (iostream)

The C++ standard `ostream` `<<` operator has been overloaded to support the output of `int_precision` objects. For example:

```
cout << "Arbitrary Precision number:" << i1 << endl;
```

The `int_precision` class also has a convert to string member function: `_int_precision_itoa(char*)`

```
int_precision i1(123);
std::string s;

s=_int_precision_itoa( &i1 );
cout << s.c_str();
```

The C++ standard `istream` `>>` operator has also been overloaded to support the input of `int_precision` objects. For example:

```
cin >> i1;
```

### Exceptions

The following exceptions can be thrown under the `int_precision` package:

# Arbitrary Precision Math C++ Package

```
bad_int_syntax      // Thrown if initialized with an illegal number
                   // For example: "123$567" is illegal because
                   // '$' is not a valid character for a numeric number.
out_of_range       // Thrown when attempting to shift with a negative
                   // value using the << or >> operator.
divide_by_zero     // Thrown if dividing by zero.
```

## Mixed Mode Arithmetic

Mixed mode arithmetic is supported in the `int_precision` class. An explicit conversion to an `int_precision` object can of course be done to avoid any ambiguity for the compiler. For example:

```
int_precision a=2;

a=a+2; // can produces compilation error: ambiguous + operator
a=a+int_precision(2); // Compiles OK
```

Be on the watch for ambiguous compiler operator errors!

## Class Internals

Most of the `int_precision` class member functions are implemented as inline functions. This provides the best performance at the sacrifice of increased program size.

The arbitrary precision integer package stores numbers as a vector of *iptype*. *iptype* is the usual 64-bit unsigned integer. This allows for more efficient use of memory and speeds up calculations dramatically. Each *iptype* can hold up to 18+19 decimal digits.

This arbitrary integer precision package was designed for ease of use and transparency rather than speed and code compactness. No doubt, there are other arbitrary integer packages in existence with higher performance and requiring fewer memory resources.

## Member Functions

The following member methods are also available:

Method	Description
<i>abs()</i>	Change the <code>int_precision</code> object to its absolute value
<i>change_sign()</i>	Reverse the sign.
<i>clz()</i>	Count leading zeros in the mBinary number
<i>ctz()</i>	Count trailing zeros in the mBinary number.
<i>even()</i>	Return true if the mBinary number is even otherwise false.
<i>flipbit()</i>	Flip a specific bit in the mBinary number
<i>iszero()</i>	Return true if the mBinary number is zero otherwise false

## Arbitrary Precision Math C++ Package

<i>number()</i>	Returns or set a copy of the mBinary field.
<i>odd()</i>	Return true if the mBinary number is odd otherwise false.
<i>pointer()</i>	Returns a pointer to the mBinary fields that contain the binary number.
<i>precision()</i>	Get or set integer precision
<i>resetbit()</i>	Reset a specific bit in the mBinary number.
<i>setbit()</i>	Set a specific bit in the mBinary number.
<i>sign()</i>	Returns or set the sign of the int_precision number. The sign bit is either +1 or -1.
<i>size()</i>	Returns the current size of the Binary elements the mBinary field holds.
<i>testbit()</i>	Test a specific bid in the mBinary number and return true or false
<i>toString()</i>	Return the Binary number as a decimal string in base 10 (default), but other bases are supported as well

### Internal storage handling

The Class `int_precision` has two public elements:

<code>int mSign;</code>	// Sign of the number. Either +1 or -1
<code>vector&lt;iptype&gt; mBinary;</code>	// The binary vector of iptype that holds the integer. Per definition, the vector when the constructor is invoked will always be initialized to zero if no argument is provided.

The *iptype* is by default set to the maximum unsigned integer *uintmax\_t* which on most systems is a 64-bit unsigned integer. This means per vector entry an *iptype* holds approximately 18-19 decimal digits. This from a storage point of view makes it much more efficient compared to the previous version which only old one decimal digit per byte. In the previous version, the number was a decimal number stored as a character in the STL library string class. While the newer binary version stores it as an STL vector of iptype. If your system doesn't support a 64-bit environment then the *uintmax\_t* is set to a 32-bit unsigned int (or you can do it manually by setting the *iptype* to an unsigned int when running in a 32-bit environment). By using the STL library vector class we can hide and don't worry about how the vector class handles memory allocation, resizing, etc. greatly simplifying the code to handle arbitrary integer precision. This also makes the source code easy to read and comprehend.

### Room for Improvement

In the latest version, I have added multi-threading to speed up the calculation of multiplication. However, due to the overhead of creating threads, it is first kicked in when numbers exceed 100,000 digits.

# Arbitrary Precision Math C++ Package

## API Methods for `int_precision`

### ***(int\_precision object).abs()***

Change the `int_precision` object to its absolute value and return it

### ***(int\_precision object).change\_sign()***

Reverse the sign and return the new sign as either -1 or +1.

### ***(int\_precision object).clz()***

Count leading zeros in the mBinary number. And return the number of zero leading bits.

### ***(int\_precision object).ctz()***

Count trailing zeros in the mBinary number and return the number of trailing zero bits

### ***(int\_precision object).even()***

Return true if the mBinary number is even otherwise false.

### ***(int\_precision object).flipbit(size\_t bitpos)***

Flip a specific bit at position bitpos in the mBinary number.

### ***(int\_precision object).iszero()***

Return true if the mBinary number is zero otherwise false.

### ***(int\_precision object).number(vector<iptype> &mb)***

Returns or set a copy of the mBinary number. If the optional parameter mb is missing, you return a copy of the current mBinary number otherwise you set mBinary to the parameter mb and return it.

### ***(int\_precision object).odd()***

Return true if the mBinary number is odd otherwise false.

### ***(int\_precision object).pointer()***

Returns a pointer to the mBinary number that contains the binary number.

### ***(int\_precision object).precision(size\_t p)***

If p is omitted, the current integer precision is returned as the number of 64bit elements, otherwise, the precision is set to p and the value returned. If a new precision is set, the number will be set to that precision. If the actual size is greater than the new precision the integer number will be truncated.

## Arbitrary Precision Math C++ Package

***(int precision object).resetbit(size\_t bitpos)***

Reset a specific bit at position bitpos in the mBinary number.

***(int precision object).setbit(size\_t bitpos )***

Set a specific bit at position bitpos in the mBinary number.

***(int precision object).sign(int newsign )***

Returns or set the sign of the int\_precision number. If called with the parameter new sign the sign is set to newsign and returned. If omitted the current sign is returned for the number. The sign is either +1 or -1.

***(int precision object).size()***

Returns the size of the Binary elements that the mBinary field currently holds. Since the mBinary field is of type vector<iptype> we just call and return the (vector object).size method.

***(int\_precision object).testbit(size\_t bitpos )***

Test a specific bid at biposition bitpos in the mBinary number and return true or false if the bit is set (1) or reset (0).

***(int precision object).toString(int base)***

Return the Binary number as a decimal STL string in base 10 (default. The parameter is optional. Otherwise in the base indicated)

## API functions for int\_precision

**int\_precision abs( const int\_precision& x); // abs(i)**

Return the absolute value of the int\_precision number x

**bool baillie\_PSW( const int\_precision& p, const bool strong) // Test number for a prime**

Test the number for a prime using the Baillie PSW primality test. Return true if it is a prime otherwise false. The parameter “strong” indicate whether to use an extra strong Lucas sequence test (strong=true). Baillie PSW is a probabilistics tester.

**int\_precision binomial( const int\_precision& n, const int\_precision& m);**

Return the binomial.  $\binom{n}{m} = \frac{n!}{m!(n-m)!}$  where  $0 \leq m \leq n$

**int\_precision factorial( const int\_precision& n); // n!**

## Arbitrary Precision Math C++ Package

Return the  $n!$  factorial

**int\_precision fibonacci( const int\_precision& n);** // Fibonacci(n)

Return the  $n^{\text{th}}$  Fibonacci sequence

**int\_precision fallingfactorial( const int\_precision& n, const int\_precision& m);** //  $n!$

Return the falling factorial.  $\frac{n!}{(n-m)!}$

**int\_precision gcd(const int\_precision& a, const int\_precision& b)** //gcd(a,b)

Return the greatest common divisor of the two numbers and b

**int\_precision ipow( const int\_precision& a, const int\_precision& b )** //  $a^b$

Return the int\_precision number a raise to the power of b.  $a^b$

**int\_precision ipow\_modulo( const int\_precision& a, const int\_precision& b, const int\_precision& c )** //  $a^{b \% c}$

Return a raise to the power of b modulo c.

**string int\_precision iptoa(const int\_precision \*a, const int base=10)**

Convert and return the int\_precision number a to an STL string using base as the base. The default is decimal base. Other valid bases are from 2..36

**bool isprime( const int\_precision& p, const int k=0)** // Test number for a prime

Test the number for a prime. Return true if it is otherwise false. This function was previously called iprime() with the same functionality. An extra optional parameter has been added and that is k. When k is zero it default to prime testing using the brute force method of testing is number via a trial division. If k is greater than zero it uses the Miller-Rabin primality tester and k is the number of rounds (or iterations) for the Miller-Rabin test. Miller Rabin is a probabilistic tester and the probability of a correct answer is  $0.25^k$ .

**int\_precision jacobi(const int\_precision& a, const int\_precision& n)**

Return the jacobi(a/n) symbol. Where a is an odd integer and n is a positive odd integer n.

**int\_precision lcm(const int\_precision& a, const int\_precision& b)** //lcm(a,b)

Return the least common multiplier of a and b

**bool miller\_rabin( const int\_precision& p, const int k=0)** // Test number for a prime

Test the number for a prime using the Miller-Rabin primality test. Return true if it is a prime otherwise false. The parameter k is the number of rounds (or iterations) for the Miller-Rabin test. Miller Rabin is a probabilistic tester and the probability of a correct answer is  $0.25^k$ .

## Arbitrary Precision Math C++ Package

**int\_precision\_stirling\_first(const int\_precision& n, const int\_precision&k, const bool sign=false)**

Return the Stirling number of the first kind  $s(n,k)$  or  $c(n,k)$ .

**int\_precision\_stirling\_first(const int\_precision& n, const int\_precision&k)**

Return the Stirling number of the Second kind  $S(n,k)$ .

**int\_precision\_stirling\_third(const int\_precision& n, const int\_precision& k, const bool sign=false)**

Return the Stirling number of the third kind  $L(n,k)$  or  $L'(n,k)$  for unsigned and signed. Stirling number of the third kind is also known as the Lah number

## Arbitrary Precision Pseudo Random number Class

The arbitrary precision random number class is a kind of subclass of the `int_precision` class. It is located in the header `iprecision.h`. This means you don't need to do anything special to get access to the class.

What the `random_precision` class does is that it uses the underlying random generators method like the ones available in the C++ standard library or others available to create an arbitrary size of a pseudo-random number. Like the built-in PRNGs in the C++ library, it is defined as a templated `random_precision` class that takes two arguments. The first is the class of the underlying PRNG and the second parameter is the type of the random number.

```
template<class _prng, class _rettype = uint64_t> class random_precision;
```

examples of declarations:

```
random_precision<mt19937_64> genmt19937_64bit;  
random_precision<mt19937,uint32_t> genmt19937_32bit;  
random_precision<ranlux24,uint32_t> genranlux24_32bit;  
random_precision<ranlux48,uint64_t> genranlux48_64bit;
```

All of the random classes in the C++ library are supported plus the following that is part of the arbitrary precision library.

Type name	Family	Return_type
<b>minstd_rand</b>	Linear congruential generator	32-bit
<b>mt19937</b>	Mersenne twister	32-bit
<b>mt19937_64</b>	Mersenne twister	64-bit
<b>ranlux24</b>	Subtract and carry	32-bit
<b>ranlux48</b>	Subtract and carry	64-bit
<b>knuth_b</b>	Shuffle linear congruential generator	32-bit
<b>default_random_engine</b>	Any of the above (implementation-defined)	32-bit or 64-bit*
<b>rand()</b>	Linear congruential generator	32-bit

## Arbitrary Precision Math C++ Package

Xoshiro family	Scramble linear	64-bit
Chacha20	"quarter round"	32-bit

The xoshiro family and chacha20 PRNG definition are in the `int_precision.h` file. Notice that the xoshiro family of PRNGs comes in four forms:

1. xoshiro256pp
2. xoshiro256ss
3. xoshiro512pp
4. xoshiro512ss

And now the next random precision number is just a call to the operator `()` using the first example:

```
genmt19937_64bit ();    // next random number
```

Now contrary to the build in PRNG that all return a fixed size of either 32-bit or 64-bit we have a different scenario with arbitrary precision. Therefore, there is an optional added parameter to the `()` operator indicating the size in bits of the maximum size of the random number returned. The `()` operator is defined as:

```
int_precision operator()(const uintmax_t bitcnt = 64)
```

where the default size is a 64-bit return type if not specified in the operator `()` call.

For example:

```
genmt19937_64bit (256);    // return a random number [0...2256-1]  
genmt19937_64bit (1000);  // return a random number [0...21000-1]
```

If the parameter is omitted it returns a random number in the range  $[0 \dots 2^{64}-1]$  which default to the size of the template parameter `_prng`.

The design of the `random_precision` class is modeled after the C++ build in PRNGs. It therefor supports the following methods.:

Method	Description
<i>(Constructor)</i>	Constructor for the <code>random_precision</code> class.
<i>discard</i>	Discard the next numbers of PRNG
<i>max</i>	Return the maximum value it can return based on the size in bits parameter
<i>min</i>	Return the minimum value (which is 0)
<i>seed</i>	Seed based on a single value of the use of the <code>seed_seq</code> class
<i>operator==</i>	Return the Boolean value of the comparison of two random generators' internal state

## Arbitrary Precision Math C++ Package

<i>operator!=</i>	Return the Boolean value of the comparison of two random generators' internal state
<i>operator()</i>	Return the next PRNG

### API Methods for `random_precision`

#### ***(random\_precision object).(Constructor)***

Takes two forms. Either we zero or one parameter indicated an initial seed value. The seed value can be an `int_precision` number or a `seed_seq` class. See the C++ reference manual for the `seed_seq` class. If no parameter is present then a default random number from the `std::random_device` is used.

#### ***(random\_precision object).discard(unsigned long long z)***

Discard the next `z` random number generated. This is equivalent to calling the `random_precision` object `operator()` `z` times.

#### ***(random\_precision object).discard(unsigned long long z)***

Discard the next `z` random number generated. This is equivalent to calling the `random_precision` object `operator()` `z` times.

#### ***(random\_precision object).min()***

Return the minimum value the `random_precision` object can return. This is zero.

#### ***(random\_precision object).max(uintmax\_t bitcount=64)***

Return the maximum value the `random_precision` object can return. Since `int_precision` can be arbitrarily large it uses the optional parameter to determine the maximum size as  $2^{\text{bitcount}} - 1$ .

#### ***(random\_precision object).seed(int\_precision& seed)***

#### ***(random\_precision object).seed(seed\_seq& seed)***

Use the seed value on the `random_precision` object. The seed value can also take the form of the parameter `std::seed_seq&`.

#### ***bool (random\_precision object).operator==(random\_precision& rhs)***

Comparing the two random precision objects for equality (same internal state). If it is the same it returns true otherwise false.

## Arbitrary Precision Math C++ Package

**bool (random *precision object*).operator!=(random\_precision& rhs)**

Comparing the two random precision objects for equality (same internal state). If it is the same it returns false otherwise true.

**int\_precision (random *precision object*).operator(uintmax\_t bitcount=64)**

Return the next random precision number maximum value the random\_precision object can return. Since int\_precision can be arbitrarily large it uses the optional parameter to determine the maximum size it can return as  $2^{\text{bitcount}}-1$ .

# Arbitrary Precision Math C++ Package

## Arbitrary Floating Point Precision Class

### Usage

To use the floating point `float_precision` class the following include statement must be added to the top of the source code file(s) in which arbitrary floating point precision is needed:

```
#include "fprecision.h"
```

The syntactical format for an arbitrary floating point precision number follows the same syntax as for regular C style single precision floating point (`float`) numbers:

*[sign][sdigit][.[fdigit]][E|e[esign][edigits]]*

*sign*      Leading sign. Either + or – or the leading sign can be omitted

*sdigit*    Zero or more significant digits

*fdigit*    Zero or more fraction digits.

*esign*     Exponent sign, can be either + or – or omitted.

*Edigits*   One or more exponent decimal digits.

Following are examples of valid `float_precision` numbers:

```
+1
1.234
-.234
1.234E+7
-E6
123e-7
```

An arbitrary floating point precision number (object) is created (instantiated) by the declaration:

```
float_precision f;
```

A `float_precision` object can be initialized at declaration (instantiation) either through its constructor or by assignment. A `float_precision` object can be initialized with an ordinary C++ built-in short, int, long, float, double, char, string data type, or even another `int_precision` or `float_precision`. For example:

```
float_precision f1(-1);           // Decimal
float_precision f2('1');          // Char. The binary value 49
float_precision f3("123.456E+789"); // String
float_precision f4(0377);          // Octal
float_precision f5(0x9Af);          // Hexadecimal
float_precision f6(0b010101);      // Binary
float_precision f7(-123.456E78);    // Float
```

## Arbitrary Precision Math C++ Package

```
float_precision f1 = -1;           // Decimal
float_precision f2 = '1';         // Char. The binary value 49
float_precision f3 = "123.456E+789"; // String
float_precision f4 = 0377;        // Octal
float_precision f5 = 0x9Af;       // Hexadecimal
float_precision f6 = 0x9Af;       // Binary
float_precision f7 = -123.456E78; // Float
float_precision f8 = f1;          // Another float_precision
float_precision f9 = int_precision(13); // Through int_precision
```

Please note that decimal string can contain ‘ or \_ to make the number more readable. E.g.

```
float_precision f10 = "-123.456'789"; // String
float_precision f11 = "-123.456_789"; // String
```

The ‘ or \_ is simply ignored by the software

Initialization with the constructor also allows precision (number of significant digits) and a rounding mode to be specified. If no precision or rounding mode is specified the default precision value of 20 significant decimal digits, and a rounding mode of *nearest* (the default behavior according to IEEE 754 floating-point standard) is used.

For example, to initialize two objects, one to 8 and the other to 4 significant digits of precision, the declarations would be:

```
float_precision f1(0,8); // Initialized to 0, with 8 digits
float_precision f2("9.87654",4);
```

In the above example, f2 is initialized to 9.877 because only four digits of significance had been specified. Please note that the initialization value of 9.87654 is rounded to the nearest 4<sup>th</sup> digit. The precision specification or default precision has precedence over the precision of the expressed value being used to initialize a float\_precision object. This behavior is consistent with standard C. For example: in the following declaration...

```
int i=9.87654;
```

the variable i is initialized to the integer value of 9 in C.

In a declaration that uses the float\_precision constructor a rounding mode can also be given. The default rounding mode is “round to nearest” (i.e. ROUND\_NEAR). However, “round up” or “round down” or “round towards zero” behaviors are also possible. See *Floating Point Precision Internals* for an explanation of rounding modes.

Here are some examples of various rounding mode behaviors.

```
float_precision PI("3.141593", 4, ROUND_NEAR); //3.142 default
float_precision PI("3.141593", 4, ROUND_UP);   //3.142
float_precision PI("3.141593", 4, ROUND_DOWN); //3.141
```

# Arbitrary Precision Math C++ Package

```
float_precision PI("3.141593", 4 , ROUND_ZERO); //3.141

float_precision negPI("-3.141593", 4, ROUND_NEAR); //-3.142 default
float_precision negPI("-3.141593", 4, ROUND_UP);    //-3.141
float_precision negPI("-3.141593", 4, ROUND_DOWN); //-3.142
float_precision negPI("-3.141593", 4 , ROUND_ZERO); //-3.141
```

## Arithmetic Operations

The following C/C++ arithmetic operators are supported in fprecision package: +, -, \*, /, %, and the unary version of + and -. Plus all the assign operators e.g. +=, -=, \*=, /=, %=

For example:

```
float_precision f1,f2,f3;

f1=f2+f3;
f2=f3/f1;
f3*=float_precision(1.5);

// Casts to standard C++ types are also supported.

Int i, double d;

i=(int)f1;      // Loss of precision may occur
d=(double)f1;   // Loss of precision may occur
```

Truncation will occur if `f1` exceeds the value of the integer or the double.

## Math Member Functions

The following set of public member functions is available for `float_precision` objects:

```
float_precision  log( float_precision );
float_precision log2( float_precision );
float_precision log10( float_precision );
float_precision exp( float_precision );
float_precision sqrt( float_precision );
float_precision pow( float_precision, float_precision );
float_precision nroot( float_precision, int );

float_precision fmod( float_precision, float_precision );
float_precision floor( float_precision );
float_precision ceil( float_precision );
float_precision modf( float_precision, float_precision );
float_precision abs( float_precision );
float_precision fabs( float_precision ); // Same as abs()
float_precision frexp( float_precision, int* );
float_precision ldexp( float_precision, int );
float_precision AGM( float_precision, float_precision );
float_precision nextafter( float_precision, float_precision );
```

# Arbitrary Precision Math C++ Package

```
// Trigonometric functions
float_precision sin( float_precision );
float_precision cos( float_precision );
float_precision tan( float_precision );
float_precision asin( float_precision );
float_precision acos( float_precision );
float_precision atan( float_precision );
float_precision atan2( float_precision, float_precision );

// Hyperbolic functions
float_precision sinh( float_precision );
float_precision cosh( float_precision );
float_precision tanh( float_precision );
float_precision asinh( float_precision );
float_precision acosh( float_precision );
float_precision atanh( float_precision );

// Miscellaneous functions
float_precision bernoulli(size_t, size_t);
```

These functions return the result in the same precision as the argument. E.g.

```
float_precision f1(0.5,10),f2(0.5,200),f3(0.5,300);

sin(f1); // return sin(0.5) with 10 digits precision
sin(f2); // return sin(0.5) with 200 digits precision
sin(f3); // return sin(0.5) with 300 digits precision
```

## Built-in Constants

The fprecision package also provides three ‘constants’:

Constant	Description
_PI	One-half the ratio of a circle’s circumference to its radius
_LN2	Natural logarithm base <sub>e</sub> of 2
_LN10	Natural logarithm base <sub>e</sub> of 10
_EXP1	e
_INVSQRT2	Inverse square root 2. 1/sqrt(2)
_SQRT2	Square root 2. Sqrt(2)
_INVSQRT3	Inverse square root 3. 1/sqrt(3)
_SQRT3	Square root 3. Sqrt(3)
_ONETENTH	1/10 to the required precision
_EULER	The Euler-Mascheroni constant
_CATALAN	The Catalan constant
_ZETA3	The Zeta(3) constant

# Arbitrary Precision Math C++ Package

These are no true C++ constants, but they are variables that can be created with varying degrees of precision. To use one of these constants, a call must be made to the function `_float_table()` to calculate (initialize) the constant to the requested precision.

The `_float_table()` function remembers the most precise constant's precision calculation and if subsequent call requests equal or less precision the constant will be truncated and rounded to the requested precision. When more precision is requested, a new calculation of the constant is preformed and stored.

For `_INVSQRT2`, `_SQRT2`, `_INVSQRT3`, `_SQRT3` the functions are implemented as newton iteration with restart from previous precision. What this means is that if we first call e.g. `_float_table(_SQRT2, 20000)`; it will go through approx. 9 iterations to reach the desired precision. If later on called with a request for 100,000 digits that normally required 13 iterations we can just restart the iterations from the 20,000 digits mark and continue up to 100,000 digits precision only requiring 4 additional iterations instead of 13.

Example usage:

```
float_precision PI;
PI=_float_table(_PI,20);    // Compute _PI to 20 digits.

PI=_float_table(_PI,10);    // No need for recalculation since
                           // the initial value was computed to
                           // 20 digits of precision.

PI=_float_table(_PI,15);    // No need for recalculation since
                           // the initial value was computed to
                           // 20 digits of precision.

PI=_float_table(_PI,25);    // Recalculation required because
                           // the initial value was computed to
                           // 20 digits of precision.
```

## Input/Output (iostream)

The C++ standard ostream << and istream >> operators have been overloaded to support output and input of `float_precision` objects. For example:

```
cout << fp1 << endl;

cin >> fp1 >> fp2;    // Input two float_precision numbers
```

## Other Member Functions

The following set of public member functions (methods) are accessible for `float_precision` objects:

```
// float_precision to String
string _float_precision_fptoa(float_precision *);
```

## Arbitrary Precision Math C++ Package

```
// float_precision to String integer
string _float_precision_fptoainteger(float_precision *);

// String to float_precision
float_precision _float_precision_atofp(char * int int);

// Double to float_precision
float_precision _float_precision_dtof(double,int,int);
```

### Exceptions

The following exceptions can be thrown under the `float_precision` package:

```
bad_int_syntax;      // Thrown if initialized with an illegal number
                    // For example: "123$567" is illegal because
                    // '$' is not a valid character for a numeric.
bad_float_syntax     // Thrown if initialized with an illegal number
                    // For example: "123.567P-3" Here P is not a valid
                    // digit or exponent prefix.
divide_by_zero       // Thrown if dividing by zero
```

### Mixed Mode Arithmetic

Mixed mode arithmetic is not supported in the `fprecision` package. An explicit conversion to a `float_precision` object is required. For example:

```
float_precision a=2;

a=a+2;      // Produces compilation error: ambiguous + operator
a=a+float_precision(2); // Compiles OK
```

Note: Be on the watch for ambiguous compiler operator errors!

### Class Internals

A `float_precision` number is stored internally as a vector of unsigned 64-bit integers or in base  $2^{64}$ . The type is typedefs to *fptype* in the header file `fprecision.h` and can be changed to port it to a different environment. From a performance perspective, it is best to set it to the maximum size of an unsigned integer. Since C++ 2011 this is *uintmax\_t* or *uint64\_t* before C++2011.

A `float_precision` value is stored normalized, that is, one binary digit before the fraction sign followed by an arbitrary number of fraction bits. Also, a normalized number is stripped of non-significant zero bits (trailing bits). This makes working and comparing floating point precision numbers easier.

# Arbitrary Precision Math C++ Package

The exponent is stored using a standard C integer variable. This is a short cut and limits the range for an exponent to  $2^{+2147483647}$  through  $2^{-2147483646}$ . This should be more than adequate for most usages.

## Member Functions

Several class public member functions are available:

change_sign()	Change the current sign of the float precision object
epsilon()	Return the epsilon for the current precision of the floating precision object, where $1.0 + \text{epsilon}() == 1.0$
exponent()	Get or set exponent
index()	Get or set the current index in the binary number. There is no check that the index is valid
inverse()	Return the inverse of the number. E.g. $1/\text{float\_object}$
mode()	Get or set rounding mode
number()	Get or set the internal mBinary number
pointer()	Return a pointer to the internal mBinary number
precision()	Get or set float precision
pred()	Return the previous representable number towards $-\infty$
sign()	Get or set sign
square()	Return the square of the float object
succ()	Return the next representable number towards $+\infty$
toExponential()	Convert float_precision to string using Exponential representation. Same as the Javascript counterpart
toFixed()	Convert float_precision to string using Fixed representation. Same as the Javascript counterpart
toFraction()	Truncate the float precision object to its fraction part
toInteger()	Truncate the float precision object to its integer part
toPrecision()	Convert float_precision to string using Precision representation. Same as the Javascript counterpart
toString()	Convert float_precision to a decimal string with an optional negative sign and exponential notation.

There is also a few functions to convert the internal representation of a float\_precision number to a C++ STL string object.

```
string _float_precision_fptoa(float_precision);
```

The \_float\_precision\_fptoa() member function is the only safe way to convert a float\_precision object without losing precision. For example:

```
float_precision f("1.345E+678");
std::string s;

s=_float_precision_ftoa(f);
cout<<s.c_str()<<endl;
```

The output from the above code fragment would be:

# Arbitrary Precision Math C++ Package

+1.345E+678

## Miscellaneous operators

Standard casting operators are also supported between `float_precision` and `int_precision` and all the base types.

```
(char)           // Convert to char. Overflow or rounding may occur
(short)          // Convert to short. Overflow or rounding may occur
(int)            // Convert to int. Overflow or rounding may occur
(long)           // Convert to long. Overflow or rounding may occur
(long long)      // Convert to long. Overflow or rounding may occur
(unsigned char)  // Convert to unsigned char. Overflow may occur
(unsigned short) // Convert to unsigned short. Overflow may occur
(unsigned int)   // Convert to unsigned int. Overflow may occur
(unsigned long)  // Convert to unsigned long. Overflow may occur
(unsigned long long) // Convert to unsigned long. Overflow may occur
(float)          // Convert to float. Overflow or rounding may occur
(double)         // Convert to double. Overflow or rounding may occur
(int_precision)  // Convert to int_precision. Overflow may occur
```

However sometimes it creates ambiguity among different compiles, so it is safer to use a method instead or use static cast in C++.

## Rounding modes

Each declared `float_precision` number has a rounding mode. The `fprecision` package supports the four IEEE 754 rounding modes:

IEEE 754 Rounding Mode	Rounding Result
to nearest	The rounded result is the closest to the infinitely precise result.
down (toward $-\infty$ )	The rounded result is the closest to but no greater than the precise result.
up (toward $+\infty$ )	The rounded result is the closest to but no less than the precise result.
toward zero (Truncate)	The rounded result is closest to but no greater in absolute value than the precise result.

The round-up and round-down modes are known as *directed rounding* and can be used to implement interval arithmetic. Interval arithmetic is used to determine upper and lower bounds for the true result of a multi-step computation when the intermediate results of the computation are subject to rounding.

The round *toward zero* mode (sometimes called the "chop" mode) is commonly used when performing integer arithmetic.

The member function that controls the rounding of `float_precision` objects is named `mode`. The `mode` member function has two (overloaded) forms: one to set the round mode of a `float_precision` object, and one to return the current rounding mode. For example:

## Arbitrary Precision Math C++ Package

```
mode=f1.mode();      // Returns rounding mode of f1
f2.mode(ROUND_NEAR); // Set rounding mode of f2 to nearest
```

Valid mode settings defined in `fprecision.h` is:

```
ROUND_NEAR
ROUND_UP
ROUND_DOWN
ROUND_ZERO
```

### Precision

Each declared `float_precision` object has its own precision setting. `float_precision` objects of different precisions can be used within the same statement involving a calculation, however, it is the precision of the L-value that defines the precision for the calculation result.

For example:

```
float_precision f1,f2,f3;

f1.precision(10);
f2.precision(20);
f3.precision(22);

f1=f2+f3; // Addition is done using 22-digit precision and the
          // result is assigned and rounded to 10-digit precision
```

Note: When using a `float_precision` object with any assignment statement (`=`, `+=`, `-=`, `*=`, `/=`, `<<=`, `>>=`, `&=`, `|=`, `^=`, etc) the left-hand side precision and rounding mode are never changed. However, there is a circumstance when a `float_precision` object can inherit the precision and rounding properties: when a `float_precision` object is declared.

For example:

```
float_precision f1(1.0, 12, ROUND_UP);
float_precision f2(f1);
float_precision f3=f1;
```

`f1` is assigned an initial value of 1.000000000000, (12-digit precision).

`f2` inherits the precision and rounding mode from `f1`.

`f3` does not inherit the precision and round of `f1`. This is a simple assignment; `f3`'s precision and rounding mode is set to the default values of 20 digits and round nearest.

Precision and rounding modes can be changed at any time using the member method for setting precision and rounding modes. For example:

## Arbitrary Precision Math C++ Package

```
f2.precision(25);    // Change from 12 to 25 significant digits
f2.mode(ROUND_ZERO); // Change from ROUND_UP to ROUND_ZERO
```

When the precision is changed, the variable is re-normalized.

When performing arithmetic operations the interim result can be of higher precision than the objects involved. For example:

+	Operation is performed using the highest precision of the two operands
-	Operation is performed using the highest precision of the two operands
*	Operation is performed using the highest precision of the two operands
/	Operation is performed using the highest precision of the two operands+1
&	Operation is performed using the highest precision of the two operands
	Operation is performed using the highest precision of the two operands
^	Operation is performed using the highest precision of the two operands

When the interim result is stored, the result is rounded to the precision of the left-hand side using the rounding mode of the stored variable.

The extra digit of precision for division insures accurate calculation. Assuming we did not add the extra digit of precision an operation like:

```
float_precision c1(1,4), c3(3,4), result(0,4);

result=(c1/c3)*c3; // Yields 0.999
```

Where the interim division yields: 0.333

By adding an extra “guard” digit of precision for division the result is more accurate.

```
result=(c1/c3)*c3; // Yields 1.000
```

The interim result of the division is 0.3333, which when multiplied by 3 gives the interim result of 0.9999 (5-digit precision). Now when rounded to 4-digit precision the result is stored as 1.000!

### Internal storage handling

Now since our arbitrary float\_precision numbers can be from a few bytes to a mostly unlimited number of bytes we would need an effective and easy way to handle large amounts of data. E.g. when you multiply two 500 digits numbers you get an interim result of 1000 digits number. We have cleverly chosen to store numbers using the STL library String class that automatically expands the String holding the number as needed. That way the storage handling is completely removed from the code since this is automatically

# Arbitrary Precision Math C++ Package

handled by the STL String class library. This trick also makes the source code easy to read and comprehend.

## Room for Improvement

In the latest version, I have added multi-threading to speed up the calculation of multiplication and the  $\pi$  constant. However, due to the overhead of creating threads, it is first kicked in when numbers exceed 100,000 digits.

## API Methods for `float_precision`

### *(float precision object).change\_sign()*

Change the current sign of the float precision object

### *(float precision object).epsilon()*

Return the epsilon for the current precision of the floating precision object, where  $1.0 + \text{epsilon}() \neq 1.0$

### *(float precision object).exponent(int expo)*

Get or set exponent of the `float_precision` object to `expo`. If `expo` is omitted the current exponent of the `float_precision` object is returned.

### *(float precision object).index(size\_t inx)*

Get or set the current index, `inx` in the vector of the `mBinary` binary number. There is no check that the index is valid

### *(float precision object).inverse()*

Return the inverse of the `float_precision` object as a new `float_precision` object.

### *(float precision object).mode(enum round\_mode rm)*

Get or set rounding mode `rm`. If `rm` is omitted the current round mode is returned otherwise the round mode is set to `rm` and returned.

### *(float precision object).number(vector<fptype> m)*

Get or set the internal `mBinary` number to `m` and returned it. If `m` is omitted the current `mBinary` number is returned.

### *(float precision object).pointer()*

Return a pointer to the internal `mBinary` number.

## Arbitrary Precision Math C++ Package

### ***(float precision object).precision(size\_t p)***

If *p* is omitted, the current precision is returned, otherwise, the precision is set to *p* and the value is returned. If a new precision is set, the number will be re-normalized.

### ***(float precision object).pred()***

Return the previous representable number towards  $-\infty$

### ***(float precision object).sign(int newsign)***

Get or set a new sign. If *newsign* is omitted the current sign is returned otherwise the float precision object is set to *newsign* and the sign is returned.

### ***(float precision object).square()***

Return the square of the float\_precision object as a new float\_precision number

### ***(float precision object).succ()***

Return the next representable number towards  $+\infty$

### ***(float precision object).toExponential(fix )***

Convert float\_precision to string using Exponential representation. Same as the JavaScript counterpart

### ***(float precision object).toFixed(fix)***

Convert float\_precision to string using Fixed representation. Same as the JavaScript counterpart

### ***(float precision object).toFraction ()***

Truncate the float precision object to its fraction part and return the integer as a *float precision object*

### ***(float precision object).toInteger()***

Truncate the float precision object to its integer part and return the fraction as a *float precision object*.

### ***(float precision object).toPrecision()***

Convert float\_precision to string using Precision representation. Same as the JavaScript counterpart.

### ***(float precision object).toString()***

Convert float\_precision to a decimal string with an optional negative sign and exponential notation.

# Arbitrary Precision Math C++ Package

## API Functions for float\_precision

**float\_precision abs( float\_precision x )**

Return the absolute value of x. Only the sign is changed to +1

**float\_precision acos( float\_precision x )**

Return the arccos(x). if x is greater than 1 or less than -1 then it throws the exception:

`float_precision::domain_error`

**float\_precision acosh( float\_precision x )**

Return the arccosh(x). if x is less than 1 then it throws the exception:

`float_precision::domain_error`

**float\_precision asin( float\_precision x )**

Return the arcsin(x). if x is greater than 1 or less than -1 then it throws the exception:

`float_precision::domain_error`

**float\_precision asinh( float\_precision x )**

Return the asinh(x).

**float\_precision atan( float\_precision x )**

Return the arctan(x).

**float\_precision atan2( float\_precision y, float\_precision x )**

Return the  $\arctan(\frac{y}{x})$ .

**float\_precision atanh( float\_precision x )**

Return the arctanh(x). ). if x is greater than or equal 1 or less than or equal -1 then it throws the exception:

`float_precision::domain_error`

**float\_precision AGM( float\_precision x, float\_precision y )**

Return the Arithmetic-Geometric mean of the two numbers as the highest precision of either x or y.

**float\_precision bernoulli( const size\_t bno, const size\_t precision )**

Return the Bernoulli number, bno with precision.

## Arbitrary Precision Math C++ Package

**float\_precision bernoulliPolynomials( float\_precision x, size\_t n)**

Return the Bernoulli Polynomials  $B(x)_n$  number in the same precision as x.

**float\_precision beta( float\_precision z, float\_precision w)**

Return the gamma function of  $\beta(z,w)$ .

**float\_precision ceil( float\_precision x )**

Return the floor of  $\lceil x \rceil$ . Returns the smallest integer that is greater than or equal to x.

**float\_precision cos( float\_precision x)**

Return the  $\cos(x)$ .

**float\_precision cosh( float\_precision x)**

Return the  $\cosh(x)$ .

**float\_precision erf( float\_precision x )**

Return the error function  $\operatorname{erf}(x)$ .

**float\_precision erfc( float\_precision x )**

Return the complementary error function  $\operatorname{erfc}(x)$ .

**float\_precision exp( float\_precision x )**

Return  $e^x$ .

**float\_precision fabs( float\_precision x )**

Return the absolute value of x. Only the sign is changed to +1. Maintained for backward compatibility

**float\_precision \_float\_table(enum table\_type t, size\_t p)**

Return the arbitrary precision constant as given by t, at the requested precision of p. See section for build-in constant.

**float\_precision floor( float\_precision x )**

Return the floor of  $\lfloor x \rfloor$ . Return the greatest integer less than or equal to x.

**float\_precision fmod( float\_precision x, float\_precision y)**

Return the remainder of the division  $x/y$ . This is the same as the modulo operator % just for the floating point.

## Arbitrary Precision Math C++ Package

**float\_precision frexp( float\_precision x, int \*expptr )**

The frexp() function breaks down the floating-point value (x) into a mantissa (m) and an exponent (n), such that the absolute value of m is greater than or equal to 1/2 and less than 2, and  $x = m * 2^n$ .

The integer exponent n is stored at the location pointed to by expptr and the mantissa is returned from the function.

**float\_precision lambertW0( float\_precision x )**

The lambert function returns the value of  $W_0(x)$

**float\_precision ldexp( float\_precision x, int exp )**

The ldexp() function returns the value of  $x * 2^{\text{exp}}$ .

**float\_precision log( float\_precision x )**

Return the  $\log_e(x)$  same as  $\ln(x)$

**float\_precision log2( float\_precision x )**

Return the  $\log_2(x)$ .

**float\_precision log10( float\_precision x )**

Return the  $\log_{10}(x)$ .

**float\_precision modf( float\_precision x, float\_precision \*intpart)**

Break the number x into two parts where the integer part is stored in the intpart and the fraction part is returned from the function.

**float\_precision nextafter( float\_precision x, float\_precision direction)**

Return the next representable number toward the direction indicated. If  $x == \text{direction}$  then the function return x

**float\_precision nroot( float\_precision x, int y )**

Return the  $\sqrt[y]{x}$ .

**float\_precision pow( float\_precision x, float\_precision y )**

Return the  $x^y$ .

**float\_precision sin( float\_precision x )**

Return the  $\sin(x)$ .

**float\_precision sinh( float\_precision x )**

Return the  $\sinh(x)$ .

## Arbitrary Precision Math C++ Package

**float\_precision sqrt( float\_precision x )**

Return  $\sqrt{x}$ .

**float\_precision tan ( float\_precision x)**

Return the tan(x). if x equal to  $\frac{\pi}{2}$  or  $\frac{3\pi}{2}$  then it throws the exception  
`float_precision::domain_error`

**float\_precision tanh( float\_precision x)**

Return the tanh(x).

**float\_precision tgamma( float\_precision x)**

Return the gamma function of x.

**float\_precision zeta( float\_precision x)**

Return the zeta function of x.

# Arbitrary Precision Math C++ Package

## Arbitrary Complex Precision Template Class

### Usage

Due to the way the C++ Standard Library template `complex` class is written, it only supports `float`, `double` build-in C++ types. The Arbitrary Precision Package “complexprecision.h” header file included in this package is also written as a template class, but it supports `int_precision` and `float_precision` classes, as well as the standard C++ built-in types.

Converting from the C++ Standard Library `complex` class to the `complex_precision`<sup>1</sup> class is accomplished simply by replacing all occurrences of `complex<ObjectName>` with `complex_precision<ObjectName>`.

Besides the traditional C operators like:

`+, -, /, *, =, ==, !=, +=, -=, *=, /=`

the following `complex_precision` member functions are available:

Member Function	Description
<code>real()</code>	Return real component
<code>imag()</code>	Return imaginary component
<code>norm()</code>	Returns <code>real*real+imaginary*imaginary</code>
<code>abs()</code>	Return sqrt of <code>norm()</code>
<code>arg()</code>	Return radian angle: <code>atan2(real, imaginary)</code>
<code>conj()</code>	Conjugation: <code>complex_precision(real,-imaginary)</code>
<code>exp()</code>	e raised to a power
<code>log()</code>	Base E Logarithm
<code>log10()</code>	Base 10 Logarithm
<code>pow()</code>	Raise to a power
<code>sqrt()</code>	Square root
<code>sin()</code>	Sine of a complex number
<code>cos()</code>	Cosine of a complex number
<code>tan()</code>	Tangent of a complex number
<code>asin()</code>	Arc Sine of a complex number
<code>acos()</code>	Arc Cosine of a complex number
<code>atan()</code>	Arc Tangent of a complex number
<code>sinh()</code>	Hyperbolic Sine of a complex number
<code>cosh()</code>	Hyperbolic Cosine of a complex number
<code>tanh()</code>	Hyperbolic Tangent of a complex number

---

<sup>1</sup> Actually, it is misleading to call it class since `complex_precision` is a template class and it knows nothing about arbitrary precision. The name `complex_precision` is used to be consistent with the naming convention used with the other Arbitrary Precision Math packages.

## Arbitrary Precision Math C++ Package

<code>asinh()</code>	Hyperbolic Arc Sine of a complex number
<code>acosh()</code>	Hyperbolic Arc Cosine of a complex number
<code>atanh()</code>	Hyperbolic Arc Tangent of a complex number

### Input/Output (iostream)

The C++ standard ostream << and istream >> operators have been overloaded to support output and input of complex\_precision objects. For example:

```
cout << cfp1 << endl;

cin >> cfp1 >> cfp2;    // Input two complex_precision number
                        // separated by white space
```

The ostream >> operator always outputs a complex number (object) in the following format:

*(realpart,imagpart)*

The istream >> operator provides the ability to read a complex precision number in one of the following standard C++ formats:

*(realpart,imagpart)*  
*(realpart)*  
*realpart*

### Using float\_precision With Complex\_precision Class Template

When a complex\_precision object is created with float\_precision objects the default rounding mode and precision attributes for float\_precision objects are used; it is not possible to specify either the rounding or precision attributes of the float\_precision components in a simple complex\_precision declaration. However, it is possible to change the rounding mode and precision attributes of a complex\_precision object float\_precision components after its assignment by using the two public member functions:

<b>Member Function</b>	<b>Description</b>
<code>ref_real()</code>	Returns a pointer to the real component
<code>ref_imag()</code>	Returns a pointer to the imaginary component

Below is an example showing how to change the precision and rounding mode of a float\_precision real component:

```
complex_precision<float_precision> cfp;
float_precision *fp;
```

## Arbitrary Precision Math C++ Package

```
fp=cfp.ref_real();
(*fp).precision(30);    // Change precision to 30 digits
(*fp).mode(ROUND_ZERO); // Change rounding mode to
                        // "Round towards Zero"
```

Note: It's poor programming practice to use different precision and rounding modes for the real part or the imaginary parts of a complex number.

If possible, `complex_precision` objects should be instantiated using a `float_precision` object for initialization. This will cause the `complex_precision` object components to inherit the precision and round mode of the initialization object. For example:

```
complex_precision<float_precision> cfp1;

complex_precision<float_precision> cfp2(cfp1); // Inherits precision and
                                                // rounding mode from cfp1

float_precision fp=cfp.real(); // Does NOT inherit precision & rounding

fp=cfp2.imag(); // Does NOT inherit the precision and round mode
```

# Arbitrary Precision Math C++ Package

## Arbitrary Interval Precision Template Class

### Usage

The `interval_precision2` class works with all C++ built-in types and concrete classes like the `complex_precision`.

```
interval_precision<float_precision> itfp;  
or  
interval_precision<int_precision> itip;
```

Besides the traditional C operators like:

`+, -, /, *, =, ==, !=, +=, -=, *=, /=`

the following `interval_precision` public member functions are available:

Member Function	Description
<code>upper()</code>	Return the upper limit of the interval
<code>lower()</code>	Return the lower limit of the interval
<code>center()</code>	Return the center of the interval
<code>radius()</code>	Return the radius of the interval
<code>width()</code>	Return the width of the interval
<code>contain()</code>	Return true if the interval is contained in another interval
<code>contains_zero()</code>	Return true if 0 is within the interval
<code>is_empty()</code>	Return true if the interval is empty. <code>lower &gt; upper</code>
<code>is_class()</code>	Return classification of the interval. ZERO, POSITIVE, NEGATIVE, MIXED

the following math `interval_precision` member functions are available:

Member Function	Description
<code>abs()</code>	Return the absolute value of the interval
<code>acos()</code>	Arc Cosine of an interval number
<code>acosh()</code>	Hyperbolic Arc Cosine of an interval number
<code>asin()</code>	Arc Sine of an interval number
<code>asinh()</code>	Hyperbolic Arc Sine of an interval number
<code>atan()</code>	Arc Tangent of an interval number
<code>atanh()</code>	Hyperbolic Arc Tangent of an interval number
<code>cos()</code>	Cosine of an interval number

---

<sup>2</sup> Actually it is misleading to call `interval_precision` a class since it does not know anything about arbitrary precision. The name `interval_precision` is used to be consistent with the naming convention used by the other Arbitrary Precision Math packages.

## Arbitrary Precision Math C++ Package

cosh()	Hyperbolic Cosine of an interval number
exp()	e raised to a power
interior()	Return true if the interval a is an interior of interval b
intersection()	The intersection of two intervals
log()	Base E Logarithm
log10()	Base 10 Logarithm
pow()	Raise to a power
precedes()	Return true if interval a precedes interval b
sin()	Sine of an interval number
sinh()	Hyperbolic Sine of an interval number
sqrt()	Square root
tan()	Tangent of an interval number
tanh()	Hyperbolic Tangent of an interval number
unionsection()	Union of two intervals

### Build-in Interval Constants

The following manifest constant is included for `interval<double>`:

```
static const interval<double> PI(3.1415926535897931, 3.1415926535897936);
static const interval<double> LN2(0.69314718055994529, 0.69314718055994540);
static const interval<double> LN10(2.3025850929940455, 2.3025850929940459);
static const interval<double> E(2.7182818284590451, 2.7182818284590455);
static const interval<double> SQRT2(1.4142135623730947, 1.4142135623730951);
```

since `interval<float>` is seldom used there are corresponding functions to convert the above interval constant to `interval<float>` :

```
inline interval<float> int_pifloat();
inline interval<float> int_ln2float();
inline interval<float> int_ln10float();
```

and for `interval<float_precision>` where the actual precision of the *float\_precision* needs to be taken into account as a parameter to these functions:

```
inline interval<float_precision> int_pi(const unsigned int);
inline interval<float_precision> int_ln2(const unsigned int);
inline interval<float_precision> int_ln10(const unsigned int);
```

### Input/Output (iostream)

The C++ standard ostream << and istream >> operators have been overloaded to support output and input of `interval_precision` objects. For example:

```
cout << ifp1 << std::endl;
cin >> ifp1 >> ifp2; // Input two interval_precision numbers
                      // separated by white space
```

## Arbitrary Precision Math C++ Package

The >> istream operator provides the ability to read an `interval_precision` object in the following standard C++ format:

`[Lowerpart,upperpart]`

The >> ostream operator writes an `interval_precision` object in the following format:

`[Lowerpart,upperpart]`

### Using `float_precision` With `interval_precision` Class Template

When an `interval_precision` object is created with `float_precision` objects the default rounding mode and precision attributes for `float_precision` objects are used; it is not possible to specify either the rounding or precision attributes of the `float_precision` components in a simple `interval_precision` declaration. However, it is possible to change the rounding mode and precision attributes of an `interval_precision` object's `float_precision` components after its assignment by using the two public member functions:

Member Function	Description
<code>ref_lower()</code>	Returns a pointer to the lower limit component
<code>ref_upper()</code>	Returns a pointer to the upper limit component

Below is an example showing how to change the precision and rounding mode of a `float_precision` component:

```
interval<float_precision> ii;
float_precision *fp;

fp=ii.ref_upper();
(*fp).precision(30);           // Changes precision to 30 digits
(*fp).mode(ROUND_ZERO);       // Change rounding mode to
                               // "Round Towards Zero"
```

Note. It is poor programming practice to use different precision and rounding modes for the lower and upper parts of an interval number.

If possible, `interval_precision` objects should be instantiated using a `float_precision` object for initialization. This will cause the `interval_precision` object components to inherit the precision and round mode of the initialization object. For example:

```
interval<float_precision> ifp1;
interval<float_precision> ifp2(ifp1);           // Inherit the precision and
                                                // rounding mode from cfp;

float_precision fp=ifp.upper(); // Does NOT inherit the precision & rounding mode
```

```
fp=ifp2.lower(); // Does NOT inherit the precision and round mode
```

# Arbitrary Precision Math C++ Package

## Arbitrary Fraction Precision Template Class

### Usage

The `fraction_precision4` class works with all C++ built-in types and the concrete class `int_precision`.

```
fraction_precision<int> fint;  
  
or  
  
fraction_precision<int_precision> fip;
```

Besides the traditional C operators like:

`+, -, /, *, ++, --, =, ==, !=, +=, -=, *=, /=`

And the Boolean operators:

`==, !=, >, <, >=, <=`

the following `fraction_precision` public member functions are available:

Member Methods	Description
<code>abs()</code>	Returns the absolute value of the fraction
<code>denominator()</code>	Set or return the denominator of the fraction
<code>inverse()</code>	Swap the numerator and the denominator. Any negative sign is maintained in the numerator
<code>isone()</code>	Test a fraction for one and return the Boolean value true/false
<code>iszero()</code>	Test a fraction for zero and return the Boolean value true/false
<code>normalize()</code>	Normalize the fraction to the standard format
<code>numerator()</code>	Set or return the numerator of the fraction
<code>reduce()</code>	Reduce and Return the whole number of the fraction
<code>whole()</code>	Return the whole number of the fraction. E.g. 8/3 is returned as 2

the following math `fraction_precision` member functions are available:

Member Functions	Description
<code>abs()</code>	Compute and return the absolute value of the fraction number
<code>bernoulli()</code>	Compute and return a Bernoulli number
<code>gcd()</code>	Compute and return the greatest common divisor of the fraction precision

# Arbitrary Precision Math C++ Package

## Input/Output (iostream)

The C++ standard ostream << and istream >> operators have been overloaded to support output and input of fraction\_precision objects. For example:

```
cout << fp1 << std::endl;
cin >> fp1 >> fp2; // Input two fraction_precision numbers
// separated by white space
```

The >> istream operator input format for a fraction is numerator '/' denominator, where the slash '/' is the delimiter between numerator and denominator.

The >> ostream operator writes an interval\_precision object in the following format:

*Numerator/Denominator*

## Using int\_precision With fraction\_precision Class Template

Like all the built-in data types in C++, e.g. from char, short, int, long, int64\_t, and the corresponding unsigned version you can also use the int\_precision class to extend the fraction to arbitrary precision.

The internal format of the fraction\_precision template class is stored in two variables  $n$  (for the numerator) and  $d$  for the denominator. Regardless of how it is initialized the fraction is always normalized, meaning there is only one minus sign if any in the fraction, and the minus sign if any is always stored in the numerator.

e.g.

```
fraction_precision<int> fp1(1,1) // internal n=1, d=1
```

```
fraction_precision<int> fp2(-1,1) // internal n=-1,d=1
```

```
fraction_precision<int> fp3(1,-1) // internal n=-1,d=1. The sign is
automatically moved to the numerator
```

```
fraction_precision<int> fp4(-1,-1) // internal n=1,d=1. The two
negative sign is cancelling out
```

If an interim arithmetic calculation results in a negative denominator it is automatically merged with the sign of the numerator as shown above in the process of normalizing the fraction. Furthermore, the fraction is always stored as the minimal representation where the greatest common divisor is automatically divided up in both the numerator and the denominator. This limit the possibility of overflow in a base type like <int>. For int\_precision it is not strictly necessary but is done to store the fraction in the least possible number of digits.

e.g.

## Arbitrary Precision Math C++ Package

```
fraction_precision<int> fp1(10,5) // After normalization it is stored  
as 2/1
```

```
fraction_precision<int> fp1(-1,9) // After normalization it is stored  
as -1/3
```

### API Methods for `fraction_precision`

***(fraction\_precision<\_Ty> object).abs()***

Return the absolute value of the fraction object.

***(fraction\_precision<\_Ty> object).denominator(\_Ty dn)***

If `dn` is omitted, the object's current denominator is returned, otherwise, the object's denominator is set to `dn` and the value is returned. If a new denominator is set, the number will be re-normalized.

***(fraction\_precision<\_Ty> object).inverse()***

The object numerator and denominator are swapped and the object is re-normalized.

***(fraction\_precision<\_Ty> object).isone()***

The object is tested for that both the numerator and denominator are one and the Boolean value of the test is returned.

***(fraction\_precision<\_Ty> object).iszero()***

The object is tested for the numerator is zero and the Boolean value of the test is returned.

***(fraction\_precision<\_Ty> object).numerator(\_Ty n)***

If `n` is omitted, the object's current numerator is returned, otherwise, the object's numerator is set to `n` and the value is returned. If a new numerator is set, the number will be re-normalized.

***(fraction\_precision<\_Ty> object).normalize()***

The object is re-normalized. Normally it will happen automatically without a need to explicitly call this method.

## Arbitrary Precision Math C++ Package

***(fraction\_precision<\_Ty> object).reduce()***

The object is reduced to a true fraction part (the numerator is less than the denominator) and the integer number is returned as a whole number. E.g.  $\frac{9}{4}$  return 2 (as the whole number) and the object is reduced to  $\frac{1}{4}$ .

***(fraction\_precision<\_Ty> object).whole()***

The whole number is returned without changing the fraction E.g.  $\frac{9}{4}$  return 2 (as the whole number) and the object is still  $\frac{9}{4}$ .

### API Functions for fraction\_precision

**template<class \_Ty> fraction\_precision<\_Ty> abs(fraction\_precision<\_Ty>& a)**

Return the absolute value of the fraction a as a new fraction\_precision number.

**fraction\_precision<int\_precision> bernoulli( size\_t bno )**

Return the Bernoulli number  $B_{bno}$ . The Bernoulli number bno will only be calculated once and then cached for subsequent calls to this function.

**template<class \_Ty> fraction\_precision<\_Ty> gcd(fraction\_precision<\_TY>& a )**

return the greatest common divisor of the fraction\_precision variable a

# Arbitrary Precision Math C++ Package

## Appendix A: Obtaining Arbitrary Precision Math C++ Package

The complete package (Precision.zip) containing the arbitrary precision classes (C++ header files and documentation) for arbitrary integer, floating point, complex and interval math can be downloaded from the following website:

[http://www.hvks.com/Numerical/arbitrary\\_precision.html](http://www.hvks.com/Numerical/arbitrary_precision.html)

{ Numerical Methods }	
<div><a href="#">Home</a> <a href="#">Polynomial Zeros</a> <a href="#">Arbitrary Precision</a> <a href="#">Numerical Ports</a> <a href="#">Papers</a> <a href="#">Related Sites</a> <a href="#">Contact us</a> <a href="#">Feedback?</a></div> <div><b>Web Tools</b> <a href="#">Polynomial Roots</a> <a href="#">Splines or Polynomial Interpolation</a> <a href="#">Numerical Integration</a> <a href="#">Differential Equations</a> <a href="#">Complex Expression Calculator</a> <a href="#">Financial Calculator</a> <a href="#">Car Lease Calculator</a></div> <div><b>Disclaimer:</b> Permission to use, copy, and distribute this software and its documentation for any non commercial purpose is hereby granted without fee, provided the software is provided "AS-IS" AND WITHOUT WARRANTY OF ANY KIND, EXPRESS, IMPLIED OR OTHERWISE, INCLUDING WITHOUT LIMITATION, ANY WARRANTY OF MERCHANTABILITY OR</div>	<div><b>Arbitrary precision package. (Revised August 2013)</b></div> <div><p>Arbitrary precision for integers, floating points, complex numbers etc. Nearly everything is here! A collections of 4 C++ header files. One for arbitrary integer precision, one for arbitrary floating point precision, a portable complex template&lt;class T&gt; and finally a portable interval arithmetic template&lt;class T&gt;. All standard C++ operators are supported plus all trigonometric and logarithm functions like exp(), log(), log10(), exp(), sin(), cos(), tan(), atan(), asin(), acos(), atan2() and of course pow() and sqrt(). Recently we added the following hyperbolic functions: sinh(), cosh(), tanh(), asinh(), acosh() and atanh(). Furthermore for each floating precision numbers the working rounding mode for arithmetic operations can be controlled. Four rounding modes are supported. Round to nearest, Round up, round down and round towards zero, makes it easy to implement interval arithmetic, which mean you can now get a precise bound of the error for every floating point calculations!</p><p>Universal constant like <math>\pi</math>, Ln 2 and Ln 10 exist in arbitrary precision. Technically the number of digits for a number that can be handle are around 4 Billions digits, however most likely you will run into system limitation before that. However we have been working with number that exceed 10-100 million digits without any issues!</p><p>Also dont forget to check out our document the math behind arbitrary precision. Click for here for <a href="#">Download</a></p><p><b>Why use this package instead of Gnu's GMP?</b></p><ul style="list-style-type: none"><li>• It has less restrictive permission rules.</li><li>• It support all relevant trigonometric, logarithms and exponential functions like exp(), log(), sin(), cos() etc. which GMP does not</li><li>• It's born as a C++ class and not a C library with a C++ wrapper.</li><li>• You also have rounding controls which GMP does not have.</li><li>• <math>\pi</math>, Ln 2, Ln 10 is available in arbitrary precision.</li><li>• Easier to use</li></ul><p><b>Why use Gnu's GMP</b></p><ul style="list-style-type: none"><li>• Because it's GNU!</li><li>• Faster and more choices on basic functions and algorithms</li><li>• Gnu's GMP can be located at: <a href="http://www.gnu.org/software/gmp/">www.gnu.org/software/gmp/</a></li></ul><p>Please note that I did not developed this package to compete with Gnu's GMP but rather because I was missing features not found in GMP, however since I get a lot of questions why? I have tried to answer it above. Have fun.</p></div> <div></div>

## Appendix B: Sample Programs

### Solving an N Degree Polynomial

The following sample C++ code demonstrates the use of the `float_precision` class and `complex_precision` class template to find every (real and imaginary) solution of an N-degree polynomial equation using Newton's (Madsen) method.

## Appendix C: int\_precision Example

This example illustrates the use and mix of int\_precision with standard types like int. It calculates the digits of  $\pi$  and returned it as a std::string.

```
std::string unbounded_pi(const int digits)
{
    const int_precision c1(1), c4(4), c7(7), c10(10), c3(3), c2(2);
    int_precision q(1), r(0), t(1);
    unsigned k = 1, l = 3, n = 3, nn;
    int_precision nr;
    bool first = true;
    int i,j;
    std::string ss = "";

    for(i=0,j=0;i<digits;++j)
    {
        if ((c4*q + r - t) < n*t)
        {
            ss += (n + '0');
            i++;
            if (first == true)
            {
                ss += ".";
                first = false;
            }
            nr = c10*(r - (n*t));
            n = (int)((c3*q + r) / t) - n;
            q *= c10;
            r = nr;
        }
        else {
            nr = (c2*q + r)*int_precision(1);
            nn = (q*(int_precision)(7*k) + c2 + r*1) / (t*1);
            q *= k;
            t *= 1;
            l += 2;
            k += 1;
            n = nn;
            r = nr;
        }
    }
    return ss;
}
```

# Arbitrary Precision Math C++ Package

## Appendix D: Fraction Example

Lambert's expression for  $\pi$  is dates back to 1770.

Lambert found the continued fraction below that yields 2 significant digits of  $\pi$  for every 3 terms.

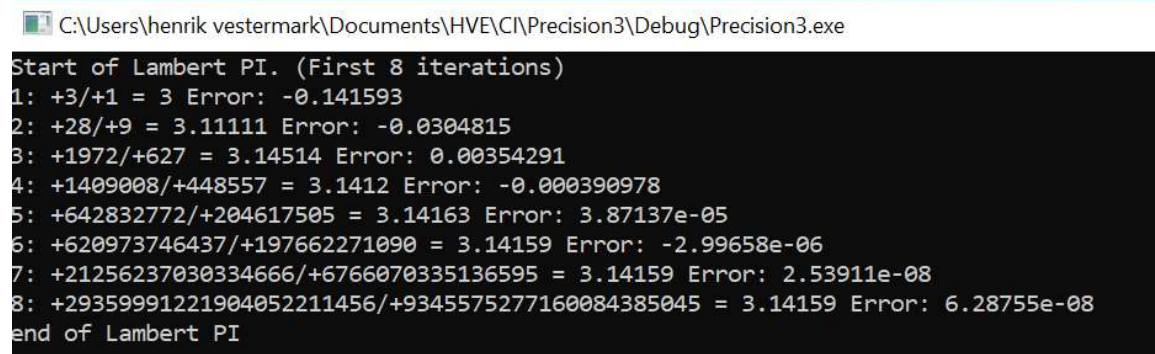

```
void continued_fraction_pi_lambert()
{
    int i,j;
    fraction_precision<int_precision> cf;
    cout << "Start of Lambert PI. (First 8 iterations)" << endl;
    for(j=1;j<=8;++j)
    {
        for (i = j; i >=0; --i)
        {
            cf += fraction_precision<int_precision>(i * 2 + 1, 1);
            if (i > 0)
                cf = fraction_precision<int_precision>(i*i, 1) / cf;
            else
                cf = fraction_precision<int_precision>(4, 1)/cf;
        }

        cout << j << ": " << cf << " = " << (double)cf << " Error: " <<
(double)cf - M_PI << endl;
    }

    cout << "end of Lambert PI" << endl;

    return;
}
```

When running it will produce the following output:

```
C:\Users\henrik vestermark\Documents\HVE\CI\Precision3\Debug\Precision3.exe
Start of Lambert PI. (First 8 iterations)
1: +3/+1 = 3 Error: -0.141593

end of Lambert PI
```

# Arbitrary Precision Math C++ Package

## Appendix E: Compiler info

This package has been developed and tested under the Microsoft visual studio version 2015-2022 in the 64-bit environment.

Furthermore, it has been tested with the GNU compiler in a 32-bit environment with Code::Blocks 20.03. In the latest version, all of the GNU warning messages have been fixed so it should compile cleanly in this environment too.

Additionally, Thanks to Robert McInnes that successfully ported these packages to the Xcode C++ environment on a Mac.

In a 32-bit environment, the max precision is  $2^{32}-1$  or the number of arbitrary digits it can handle, however, most likely you will run into an Operative system dependent constraint long before the theoretical limit. In a 64-bit environment, the max precision would be  $2^{64}-1$
